Midpoint evaluation for CMA-ES

Karol Opara

January 2, 2014

Abstract

CMA-ES is one of the state-of-the art evolutionary algorithms. It consists of sampling from multivariate normal distribution, whose covariance matrix is claimed to approximate the inverse hessian of the objective function. The midpoint of this distribution should be therefore the best linear unbiased estimator of the optimum. This hypothesis was tested on the BBOB 2013 benchmark set using the standard CMA-ES implementation. Evaluation of the objective function in the midpoint neither improves nor deteriorates the performance of the algorithm. Moreover, it turns out that the standard implementation of CMA-ES is competitive but not as good as the best CMA-ES variants, which took parts in the BBOB 2009 competition.

1 Introduction

Covariance Matrix Adaptation Evolution Strategy (CMA-ES), introduced in [7] is one of the state-of-the-art evolutionary algorithms [5]. The method consists of iterative sampling from a multivariate normal distribution $\mathcal{N}(\mathbf{m}^{(g)}, \sigma^{(g)}\mathbf{C}^{(g)})$. Its parameters, mean $\mathbf{m}^{(g)}$, covariance matrix $\mathbf{C}^{(g)}$ and the scaling factor $\sigma^{(g)}$ are updated based on the values of the objective function to obtain a better-adapted multivariate normal distribution in iteration $g + 1$.

The series of mean values in consecutive iterations $\mathbf{m}^{(g)}, \mathbf{m}^{(g+1)}, \mathbf{m}^{(g+2)}, \dots$ is not directly used in the CMA-ES algorithm. The best of the sampled points is treated as an estimate of the optimum. The authors of CMA-ES claim there is “strong empirical evidence” that the covariance matrix in this algorithm approximates the inverse hessian [2]. In such case, for locally spherical functions location of the population mean would be the best linear unbiased estimator of the optimum (according to the Gauss-Markov theorem).

Therefore it might be beneficial to compute the value of the fitness function in the midpoint. Similar approach proved effective in a study of Differential Evolution by Arabas. He suggests that the midpoint should not be added to the population due to the risk of premature convergence but only used to update the estimate of the best point.

To verify the hypothesis of usefulness of midpoint evaluation for CMA-ES an experiment was performed. The standard implementation of CMA-ES [3]

(version 3.62 beta, retrieved in December 2013) was compared with a variant, which was evaluating the midpoint in every tenth iteration ($p_e = 10$). Comparison was performed for computational budget of $D \cdot 10^4$ function evaluations, where D is the dimensionality of the search space. Evaluation was based on the BBOB 2013 benchmark.

2 Results

Results from experiments according to [4] on the benchmark functions given in [1, 6] are presented in Figures 3, 4, 5, 2, 2, and Tables 1 and 2. The **expected running time** (ERT), used in the figures and table, depends on a given target function value, $f_t = f_{\text{opt}} + \Delta f$, and is computed over all relevant trials as the number of function evaluations executed during each trial while the best function value did not reach f_t , summed over all trials and divided by the number of trials that actually reached f_t [4, 8]. **Statistical significance** is tested with the rank-sum test for a given target Δf_t using, for each trial, either the number of needed function evaluations to reach Δf_t (inverted and multiplied by -1), or, if the target was not reached, the best Δf -value achieved, measured only up to the smallest number of overall function evaluations for any unsuccessful trial under consideration if available.

3 Conclusions

Results presented in section 2 show that there is hardly any difference between the two investigated variants of the CMA-ES. This means, that evaluation of the midpoint neither improves nor deteriorates the performance of this algorithm. Hence, it may be skipped to avoid unnecessary complications without bringing any difference in performance.

The empirical runtime cumulative distribution function plot Fig. 3 presents the performance of the reference implementation of CMA-ES [3] (thick, red line) and all algorithms, which took part in the BBOB 2009 contest (thin beige lines). The higher the area under each curve the better the performance of an algorithm. The reference CMA-ES implementation is quite competitive but not as good as the best algorithms from 2009 contest, which also included variants of CMA-ES [5].

References

- [1] S. Finck, N. Hansen, R. Ros, and A. Auger. Real-parameter black-box optimization benchmarking 2009: Presentation of the noiseless functions.

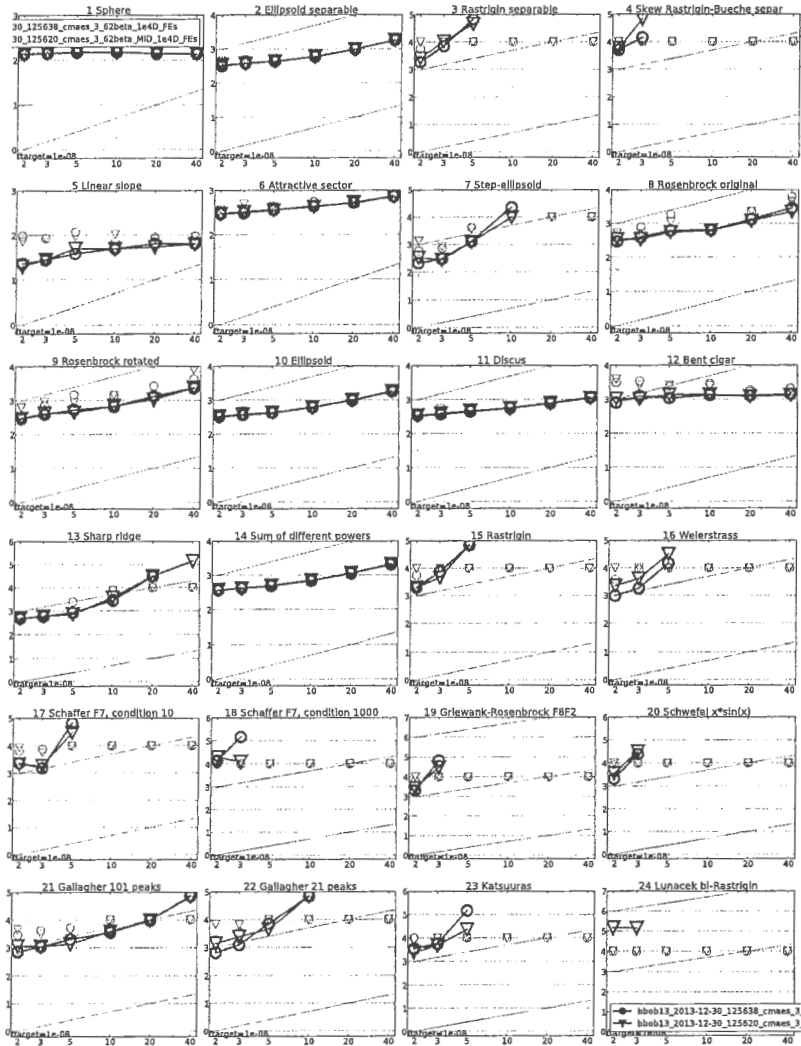

Figure 1: Expected running time (ERT in number of f -evaluations) divided by dimension for target function value 10^{-8} as \log_{10} values versus dimension. Different symbols correspond to different algorithms given in the legend of f_1 and f_{24} . Light symbols give the maximum number of function evaluations from the longest trial divided by dimension. Horizontal lines give linear scaling, slanted dotted lines give quadratic scaling. Black stars indicate statistically better result compared to all other algorithms with $p < 0.01$ and Bonferroni correction number of dimensions (six). Legend: \circ :CMA-ES, ∇ :CMA-ES MID.

Expected running time (ERT in \log_{10} of number of function evaluations) of CMA-ES (x -axis) versus CMA-ES MID (y -axis) for 46 target values $\Delta f \in [10^{-8}, 10]$ in each dimension on functions f_1 - f_{24} . Markers on the upper or right edge indicate that the target value was never reached. Markers represent dimension: 2: \cdot , 3: ∇ , 5: \star , 10: \circ , 20: \square , 40: \diamond .

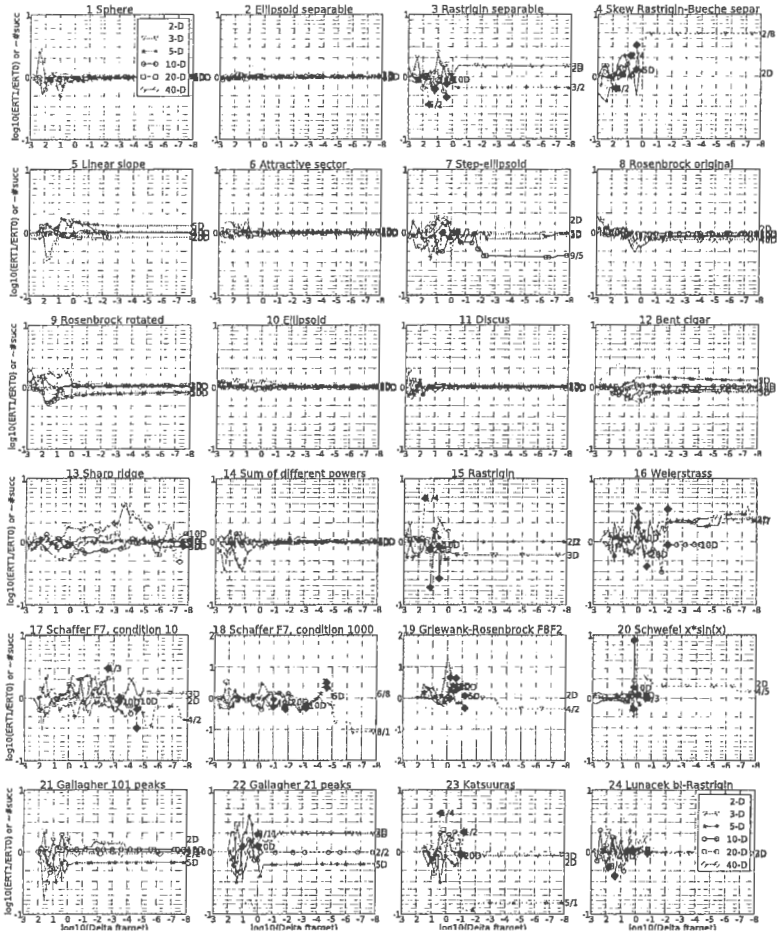

Figure 2: Ratio of ERT for CMA-ES MID over ERT for CMA-ES versus $\log_{10}(\Delta f)$ in 2: \bullet , 3: ∇ , 5: $*$, 10: \circ , 20: \square , 40-D: \diamond . Ratios $< 10^0$ indicate an advantage of CMA-ES MID, smaller values are always better. The line becomes dashed when for any algorithm the ERT exceeds thrice the median of the trial-wise overall number of f -evaluations for the same algorithm on this function. Filled symbols indicate the best achieved Δf -value of one algorithm (ERT is undefined to the right). The dashed line continues as the fraction of successful trials of the other algorithm, where 0 means 0% and the y-axis limits mean 100%, values below zero for CMA-ES MID. The line ends when no algorithm reaches Δf anymore. The number of successful trials is given, only if it was in $\{1 \dots 9\}$ for CMA-ES MID (1st number) and non-zero for CMA-ES (2nd number). Results are significant with $p = 0.05$ for one star and $p = 10^{-\#\star}$ otherwise, with Bonferroni correction within each figure.

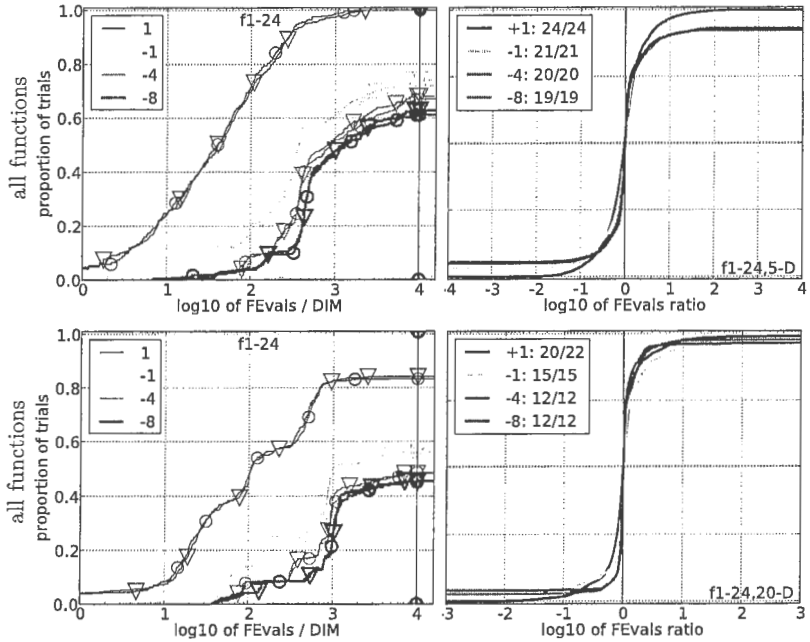

Figure 3: Noiseless functions 5-D (top) and 20-D (bottom). Left: Empirical Cumulative Distribution Function (ECDF) of the running time (number of function evaluations) for CMA-ES MID (\circ) and CMA-ES (∇), divided by search space dimension D , to fall below $f_{\text{opt}} + \Delta f$ with $\Delta f = 10^k$ where k is the value in the legend. The vertical black lines indicate the maximum number of function evaluations. Light beige lines in the background show ECDFs for target value 10^{-8} of all algorithms benchmarked during BBOB 2009. Right subplots: ECDF of ERT of CMA-ES MID over ERT of CMA-ES for different Δf .

Figure 4: Subgroups of functions 5-D. See caption of Figure 3.

Figure 5: Subgroups of functions 20-D. See caption of Figure 3.

Table 1: ERT in number of function evaluations divided by the best ERT measured during BBOB-2009 given in the respective first row with the central 80% range divided by two in brackets for different Δf values. #succ is the number of trials that reached the final target $f_{\text{opt}} + 10^{-8}$. 1:CMA-ES is CMA-ES and 2:CMA-ES MID is CMA-ES MID. Bold entries are statistically significantly better compared to the other algorithm, with $p = 0.05$ or $p = 10^{-k}$ where $k \in \{2, 3, 4, \dots\}$ is the number following the \star symbol, with Bonferroni correction of 48. A \downarrow indicates the same tested against the best BBOB-2009. Results for 5D.

the 1990s, the number of people who have been employed in the public sector has increased in all countries. The increase has been particularly large in the United States, where the public sector has grown from 10.5% of the total workforce in 1970 to 17.5% in 1995 (see Figure 1).

There are a number of reasons for the increase in public sector employment. One reason is that the public sector has become a more attractive place to work. This is due to a number of factors, including the fact that public sector jobs are often more secure and offer better benefits than private sector jobs. Another reason is that the public sector has become a more important part of the economy. This is due to the fact that the public sector has become a major provider of social services, such as education, health care, and social security.

The increase in public sector employment has had a number of effects on the economy. One effect is that it has helped to reduce unemployment. This is because the public sector has created a large number of new jobs. Another effect is that it has helped to reduce income inequality. This is because public sector jobs are often higher paying than private sector jobs. Finally, the increase in public sector employment has helped to reduce the size of the private sector. This is because the public sector has become a more important part of the economy.

There are a number of challenges facing the public sector in the future. One challenge is that the public sector is facing a large increase in demand for social services. This is due to the fact that the population is aging and there are more people who need social services. Another challenge is that the public sector is facing a large increase in costs. This is due to the fact that the cost of providing social services is increasing. Finally, the public sector is facing a large increase in competition from the private sector. This is due to the fact that the private sector is becoming a more important part of the economy.

There are a number of ways in which the public sector can meet these challenges. One way is to increase efficiency. This can be done by reducing waste and improving the way in which services are provided. Another way is to increase revenue. This can be done by raising taxes or by selling public assets. Finally, the public sector can meet these challenges by increasing competition from the private sector. This can be done by allowing private companies to provide social services.

The public sector is an important part of the economy and it is facing a number of challenges in the future. It is important that we find ways to meet these challenges so that the public sector can continue to provide the social services that we need. This will require a combination of increased efficiency, increased revenue, and increased competition from the private sector.

The public sector is an important part of the economy and it is facing a number of challenges in the future. It is important that we find ways to meet these challenges so that the public sector can continue to provide the social services that we need. This will require a combination of increased efficiency, increased revenue, and increased competition from the private sector.

The public sector is an important part of the economy and it is facing a number of challenges in the future. It is important that we find ways to meet these challenges so that the public sector can continue to provide the social services that we need. This will require a combination of increased efficiency, increased revenue, and increased competition from the private sector.
