(Received 13 February 1997, Accepted 15 March 1999)

Abstract – From the second half of the 19th century up to the present time 600 macroinvertebrate taxa were found in the Vistula. Most data concern Chironomidae (152 taxa), Oligochaeta (64), Trichoptera (57), Ephemeroptera (50), and Mollusca (50). Numerous groups, however, have not been investigated or are known only to a very small degree. Also the degree of determination of the fauna was not the same in various reaches of the river. The collected data document that the pollution of the River Vistula and the construction of dam reservoirs and of a system of cascades brought about a dramatic reduction in the number of species and caused change in the composition of the fauna.

Key words: River Vistula, benthic macroinvertebrates, biodiversity, river pollution.

1. Introduction

The River Vistula is among those Polish rivers which are poorly known in the hydrobiological aspect. So far, apart from the routine controls of the degree of pollution (Florczyk et al. 1971, 1972, Jarmolińska et al. 1975, 1981, Fila et al. 1986, Dojlido and Woyciechowska 1989, Korol et al. 1994) a comprehensive hydrobiological study of this river is still lacking. Great research projects undertaken in the 40's (Staff and Sakowicz 1951) and then in the 80's (the "Vistula Programme") did not contribute any significant results. There are available a fairly large number of fragmentary studies conducted in various reaches of the Vistula, though their results are scattered in numerous Polish and foreign journals (Kownacki et al. 1994). On the basis of the accessible literature a few attempts were made to recapitulate the current hydrobiological knowledge concerning the Vistula and its catchment basin (Kajak 1983, Dynowska and Maciejowski 1991). In some papers the fauna of bottom macroinvertebrates was taken into consideration (Szczęsny 1991), but the fauna of the Vistula was treated as a marginal problem, the investigation being concentrated on its tributaries. Thus, it seemed necessary to recapitulate the scattered information concerning bottom macroinvertebrates of the Vistula.

The aim of the present work was to list all the bottom macroinvertebrate taxa in the Vistula from the second half of the 19th century (Friedel 1885, Wierzejski 1885, 1888) to 1998 and if possible to demonstrate the changes in the fauna of this river under the impact of human activity. The list includes the bottom macrofauna

of the River Vistula from its sources to the Baltic Sea. Also the fauna of ox-bow lakes and river arms directly connected with this river and of reservoirs and water stages constructed on it were taken into consideration. The fauna of dam reservoirs was not separately listed. In the case of all the reservoirs and water stages on the Vistula no investigation had been conducted before their construction or at least no results of such studies were published. Therefore it was not possible to make any reliable comparisons. On the other hand, as far as the available literature permitted, changes in the fauna of macroinvertebrates induced by pollution or other kinds of human activity were stressed.

2. Study area, material, and methods

The greatest Polish River, the Vistula, is 1047 km long and its drainage basin covers $194.4 \cdot 10^3$ km². The river originates from two streams, the Biała Wisełka and Czarna Wisełka, flowing out of sources lying on the slopes of Mount Babia Góra (Beskid Śląski Mts, the Carpathians) at an altitude of about 1100 m.

Already in its initial course the Vistula receives considerable loads of pollution from the localities of Wisła, Ustroń, and Skoczów. Further important sources of pollution are the River Biała (wastes from Bielsko-Biała), River Przemsza (wastes from the Upper Silesian Industrial Region), and also municipal and industrial wastes from Oświęcim, Cracow, Tarnobrzeg, the nitrogen factory in Puławy, chemical plants in Pionki, the city of Warsaw, Płock, Włocławek, Toruń, Mątwy, and Bydgoszcz. In 1992 only the source reaches of the Vistula might have been classed as quality class I (Korol et al. 1994), this constituting 3.5% of the entire river course. Waters of quality class II were found in 29.1% of the river, of in quality class III in 14.6%, while those outside quality classification constituted 52.7% of the river course.

A number of dam reservoirs and water stages were constructed on the Vistula: in the upper course the Wisła-Czarne Reservoir, the Goczałkowice Reservoir with a cascade composed of several water stages (Łączany, "Kościuszko", Dąbie, Przewóz) and in the lower river course the Włocławek Reservoir. No hydrotechnical constructions were introduced in the middle reach of the Vistula and it has preserved its natural character to a considerable degree. The entire length of the River Vistula was divided into ten reaches (Fig. 1) which are listed below. The length of the reaches was determined on the basis of data given by Czarnecka et al. (1978), with the source of the Czarna Wisełka stream accepted as kilometre 0.0 (in the paper quoted above the 0.0 km is the confluence of the Rivers Vistula and Przemsza).

1. Czarna Wisełka (9.1 km) and Biała Wisełka (6.2 km), the Wisła-Czarne Reservoir, and the reach above Goczałkowice Reservoir up to the closed river gauge "Strumień" (0.0–50.1 km).
2. The Goczałkowice Reservoir and the reach of the Vistula to the mouth of the River Przemsza (50.1–106.2 km).
3. The reach from the Przemsza outflow to the river gauge "Kraków-Bielany" above the city of Cracow, with the water stages Łączany and "Kościuszko" (106.2–175.4 km).
4. The reach from the river gauge "Kraków-Bielany" to the outflow of the River Dunajec; here belongs the reach within the city of Cracow with water stages Dąbie and Przewóz (175.4–266.8 km).

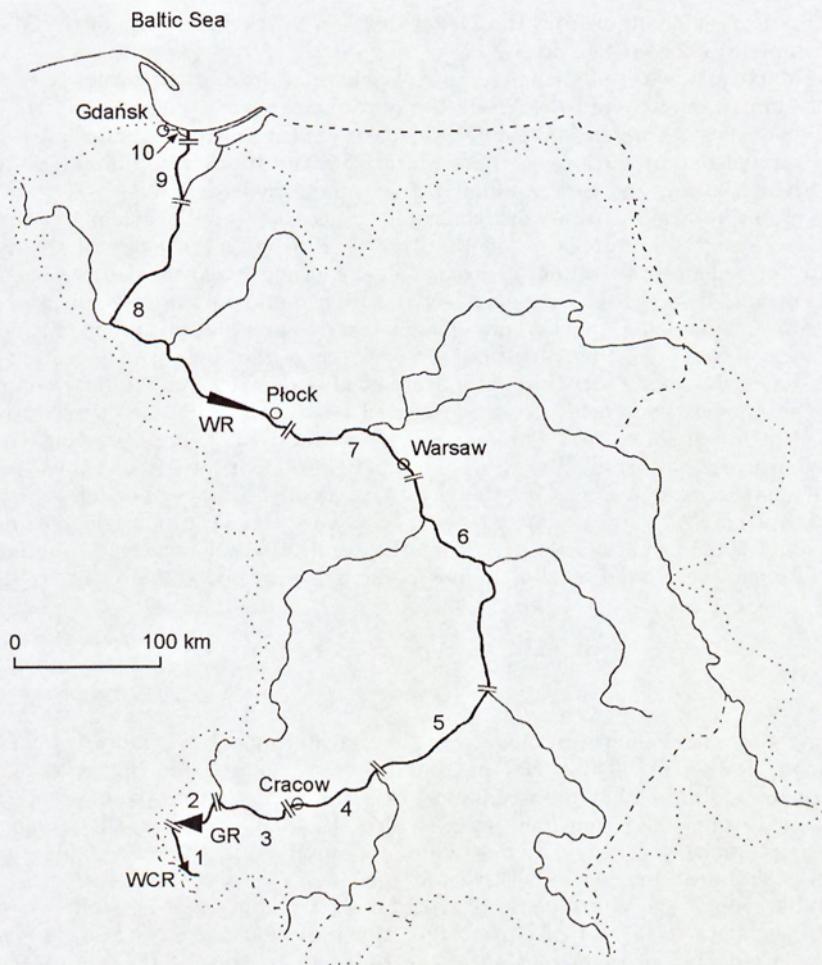

Fig. 1. Division of the River Vistula into reaches (1–10): GR – Goczałkowice Reservoir, WCR – Wista-Czarne Reservoir, WR – Włocławek Reservoir (dotted line – the Vistula watershed). In the Cracow region the cascade composed of four water stages (Łączany, "Kościuszko", Dąbie, and Przewóz) was not marked.

5. The reach from the outflow of the River Dunajec to that of the River San (266.8–385.9 km).
6. The reach from the outflow of the San to the outflow of the River Jeziorka above the city of Warsaw (385.9–599.9 km).
7. The reach from the mouth of the Jeziorka to the planned water stage Płock lying above the town of Płock; here belongs the reach within the Warsaw agglomeration (599.9–732.2 km).
8. The reach from the Płock water stage to the Nogat arm division (the beginning of the Vistula river delta); this reach includes the Włocławek Reservoir (732.2–992.8 km).

9. The main river channel from the Nogat division to the beginning of the Martwa Wisła channel (992.8–1042.2 km).

10. The Martwa Wisła (the former main river channel flowing out to the Baltic Sea, about 27 km in length) and the Wista Śmiała (about 3 km).

This division has a conventional and subjective character. It was chiefly based on studies carried out by various authors (data from the literature), on the pollution of the River Vistula, and to a smaller degree on the hydrography.

The materials used in the work consisted of accessible publications, typescripts (expertise reports) deposited in the Institute of Freshwater Biology of the Polish Academy of Sciences or rendered accessible by other research centres, and unpublished data from various experts. All the taxa found in the above works were taken into consideration apart from evident errors or previously published revisions questioning the given identification. In this case the taxon in question was regarded as erroneously identified and appropriately marked. An attempt was made to use the current nomenclature, the accepted basis being the works by Razowski (1991a, 1991b, 1997a, 1997b). The only synonyms used were those previously given in the literature concerning the River Vistula. The nomenclature of Chironomidae was particularly troublesome. Most determinations of the *ex grege* or *forma larvalis* type have a generic value today. A few species only can be properly identified on the basis of their larval stages. If within the genus several taxa were quoted, the Roman figures were used, earlier names being given in brackets.

3. Results

Along the entire length of the River Vistula 600 macroinvertebrate taxa have been identified so far (Table I). This number does not include higher taxonomic units (genera, families) if more detailed determinations were given within their limits, or erroneously identified taxa, which are also given in the Table with successive numbers. The synonyms were not numbered. A total of 684 taxa of various systematic grades and correctness of identification are listed. The most numerous groups are Chironomidae (152 taxa), Trichoptera (57), Ephemeroptera (50), Oligochaeta (64), and Mollusca (50). However, most groups are very poorly known. The degree of investigation of the separate reaches of the Vistula is also strongly varied. The fauna of the upper course of the river from its sources to the Goczałkowice Reservoir (reach 1) has been fairly thoroughly investigated. This also concerns the Goczałkowice Reservoir (reach 2), the River Vistula within the Cracow area (reach 4), the Warsaw region (reach 7), the Włocławek Reservoir (reach 8), and the old outflow reach of the Vistula (reach 10). On the other hand, the middle course of the River from the outflow of the Dunajec to the city of Warsaw (reaches 5 and 6) are poorly known. Also the knowledge of the separate groups of the fauna in various reaches of the Vistula is not uniform. For example, the number of taxa of the fairly well investigated group of Ephemeroptera varies in the different reaches from 19 (reach 1) and 22 (reach 9) to 0 (reaches 5 and 10).

5. Discussion

The number of 600 taxa determined in the River Vistula, its arms and dam reservoirs is not large, if the size of the river and variety of habitats are taken into consideration. The comparison of the fauna in the Vistula with the list of animals in Poland (Razowski 1990, 1991a, 1991b, 1997a, 1997b) suggests that the river is poorly known in the faunal aspect. The number of Oligochaeta and Trichoptera found in it only reaches a 50% share in the total number of taxa found in Poland, while Chironomidae do not reach more than 35% and Trichoptera 25%. The degree of knowledge of the remaining groups is even lower. Numerous determinations originated in the 19th century and have not yet been verified, e.g. Porifera (Wierzejski 1885) or Bryozoa (Wierzejski 1888).

The pollution of the river and changes in the character of its hydrology induce significant changes in the composition of fauna in the Vistula. Currently a decline in numerous species is observed in the most polluted reaches of the river. Within the Cracow region all the Ephemeroptera, Plecoptera, and Trichoptera have disappeared although their occurrence was still recorded in the 40's (Starmach 1948). On the other hand, the numbers of Oligochaeta have increased, reaching 63–99% of the entire fauna (Dumnicka and Kownacki 1988). The construction of dam reservoirs has also affected natural zoocoenoses, bringing about the decline of numerous species. In the Wisła-Czarne Reservoir, fed with waters of the Biala Wisełka and Czarna Wisełka, the zoobenthos is chiefly composed of Oligochaeta (*Limnodrilus hoffmeisteri* and *Tubifex tubifex*), and less numerous Chironomidae (*Procladius* spp., *Ablabesmyia* sp., *Prodiamesa olivacea*, *Dicrotendipes* sp., and *Chironomus* sp.) (Krzyżanek 1991). On the other hand, the typical fauna of the streams of the upper Vistula of a great taxonomic diversity with Ephemeroptera, Trichoptera, Chironomidae (chiefly Orthocladiinae), and Simuliidae dominating (Mikulski 1950, Szczęsny 1986, 1995, Boklak et al. 1993, Kownacki 1995), does not occur in that reservoir. The construction of cascades has brought about a further impoverishment of the species diversity even in the most polluted reach of the Vistula between Oświęcim and Cracow. In the reservoir at the Łączany water stage (km 144th of the Vistula course) Oligochaeta, chiefly *Limnodrilus hoffmeisteri*, constitute 99.9% of the bottom fauna while in the non-regulated reach above the reservoir (km 159) the diversity of the fauna is much greater in spite of a similar load of pollution (Kownacki 1988). It is true that Oligochaeta still dominate there, but they constitute only 63% of the numbers of the total fauna, Chironomidae are fairly numerous (34%), Hirudinea and Gastropoda occur constantly, and single individuals of Amphipoda, Simuliidae, Chaoboridae, Psychodidae, and Coleoptera may be encountered.

Acknowledgements – The author would like to express his gratitude to all those persons who reviewed the manuscript and introduced valuable comments to this paper. He wishes to thank Professor Eugeniusz Biesiadka for making accessible unpublished data on Hydracarina from the Włocławek Reservoir and the Vistula, and Miss Joanna Zielonka, MSc for the unpublished data concerning the fauna of the lower reach of the River Vistula from the years 1971–1982. He is deeply obliged to Professor Krzysztof Jaźdżewski for his inspection of the list of taxa and the introduction of notes about Crustacea in the Vistula. Also to be thanked is Dr Elżbieta Dumnicka for her critical review of Oligochaeta and for supplementing the list with species found in the study on the upper Vistula course in 1997–1998. He is also grateful to Dr Stefan Mielewczyl for correcting the nomenclature of Coleoptera and Odonata, Dr Jacek Siciński for his comments to Polychaeta, and Dr Alicja Konopacka for the review of Porifera. Finally, thanks are due to Drs Bronisław Szczęsny and Stanisław Czachorowski for their help in preparing the list of Trichoptera, and to Professor Ryszard Szadziewski for suggesting additional materials concerning Diptera.

² All the information concerning the occurrence of this species reported before 1959 must be regarded as uncertain (Jaźdżewski and Konopacka 1995).

³ All the information concerning the occurrence of this species derived before 1959, and even later ones, must be regarded as dubious since its occurrence in the middle course of the Vistula, is highly improbable (Jaźdżewski and Konopacka 1995).
